COLUMBIA UNIVERSITY IN THE CITY OF NEW YORK

Economic Report and Production Analysis for Malaysia

0. Executive Summary

In this report, we aim to uncover the economic path Malaysia went through during the period from 2009 to 2014. Specifically, we dive into the topic through a macroeconomic overview of Malaysia from the perspective of Gross Domestic Product (GDP) and Economic Complexity Index (ECI), which reflect countries' production capability and production structure, respectively. We find that during the period of our interest, Malaysia demonstrated a surprising level of economic growth with an annual GDP growth rate of 10.8%, concurrent with an increase in economic complexity as compared with other major Asian or emerging economies in the world.

The amazing progress made during the period, we believe, can be largely explained through analysis of the economic and product complexity structure of Malaysia on the industry group level. The product classification system we adopt allow us to measure the actual development for various industry groups and to observe that Malaysia strategically invested in developing basic industry groups such as stone, food and chemicals during the period, while its Asian counterparts and emerging economies around the globe have adopted much more aggressive growth paths.

Based on our analysis of the opportunity gain and a sensitivity analysis of major industry groups, Malaysia could further its gains by staying optimal with its current industry structure and there is no immediate need of reform because no industry has a positive opportunity gain at its current stage. We further note that Malaysia has a slightly mismatched development strategy that indicates a moderate level of fitness with the strategy calculated on a complexity level, having an adjusted R-square of around 10.8%. Since a significant positive correlation exists between five-year GDP growth and the structural optimality index of an economy as we define and calculate, Malaysia indeed adopted a promising but not perfect development plan as compared with other emerging economies both on a regional scale and on a global scale, and has the potential to further its economic gains through industrial structure balancing as suggested in the paper.

1. Report Overview

In this report, we aim to uncover the economic path Malaysia went through during the period from 2009 to 2014. Specifically, we dive into the topic through a macroeconomic overview of Malaysia from the perspective of Gross Domestic Product (GDP) and Economic Complexity Index (ECI), which reflect countries' production capability and production structure, respectively. We then analyze the industrial framework and changes of Malaysia during the period based on quantitative measures such as Product Complexity Index (PCI) and Product Family Complexity Index (PfCI), followed by a detailed analysis of how such changes have matched with development strategies as quantitatively measured by opportunity gains on an industry-level. We conclude our report with macro-level results and predictions of Malaysia, as deduced from regression models we have established on a global scale, which takes into account countries' stances in their product space.

2. Macroeconomic Results

2.1 GDP Ranking and Changes

As the 36th largest economy in the world by GDP, Malaysia has a GDP of 202billion USD in 2009 and 338billion USD in 2014, exhibiting a promisinglevel of economic output. Figure 1 illustrates the time-series GDP results for majoremergingeconomies from 1996-2016, and Malaysiaranks among its peers as a small but growing economy in terms of both GDP and GDP growth.The effect is particularly prominent for the period from 2009 to 2014, during which Malaysiaachieved an annual growth of 10.8% in GDP.This number is above the annual growth rate of the other five leading emerging economies, which have a geometric average growth rate of 9.2% and an arithmetic average growth rate of 9.5%. Comparing with more developed economies in a global scale, the annual growth rate of 10.8% is even more staggering since countries such as USA have an annual GDP increase of merely around 3.9% during the period. The rapid economic growth, we believe, can be reflected through changes in ECI and PCI, and can be further explained by a well-chosen set of production strategies adopted by Malaysiafrom 2009 to 2014, which we will expand at the later stage of the report.

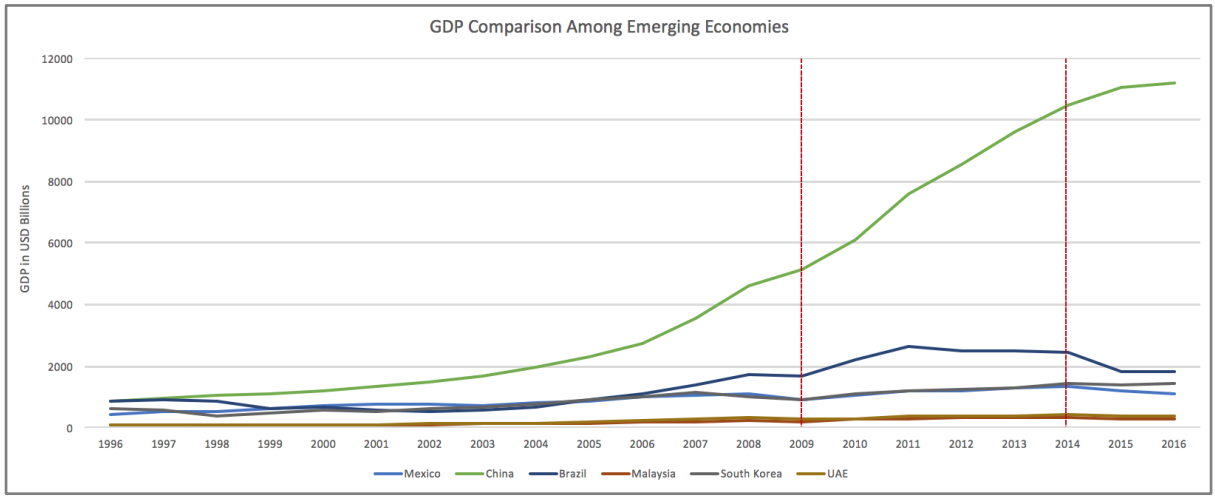

Figure 1: GDP Comparison Among Major Emerging Economies

2.2 ECI Ranking and Changes

The Economic Complexity Index (ECI), as defined by Ricardo Hausmann and Cesar Hidalgo in 2009 to explain the knowledge accumulated in a country's population, exhibits similar pattern for Malaysia. As illustratedinFigure 2 below, Malaysia exhibits a noticeable increase in terms of its production capability from 2009 to 2014, as measured by ECI. This is in direct contrast to countries such as Brazil and Mexico, which demonstratea disadvantage in both ECI growth rate and GDP growth rate.

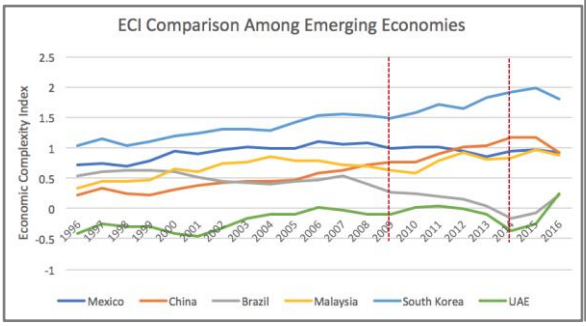

Figure 2: ECI Comparison

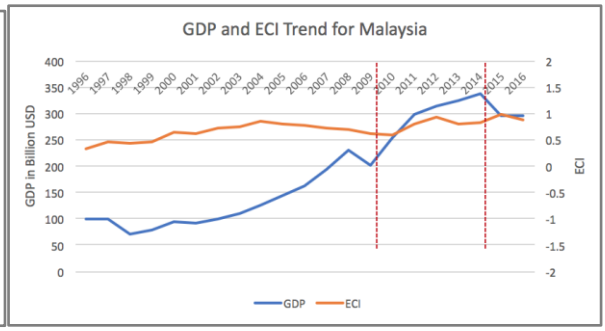

Figure 3: GDP and ECI (Malaysia)

Figure 3 offers a further comparison of GDP and ECI over the entire time span from 1996 to 2016 for Malaysia. Based on statistical analysis, ECI is a significant covariate for GDP with an adjusted R-square of 40.0%. In particular, the increase in GDP during the period from 2009 to 2014 is accompanied by an increase in ECI, indicting the potential that the mild economic growth experienced by Malaysia during the period from 2009 to 2014 might be attributed to its improving ECI, or the effectiveness of the country in developing a competitive product space that helps to accumulate complicated knowledge and technology. In order to provide a more concrete answer to why this has happened, we will dive into an analysis of Malaysia's production structure and its product space designs in the next few chapters.

3. ProductionAnalysis

3.1 Product Categorization

Our main data source in this research is the UN Comtrade Website (https://comtrade.un.org), which provides us with valuable information on countries' export values on an annual basis, including highly specific export data for more than 5000 categories of products. In order to have a holistic vision of the product space of a country, however, a level of categorization is required. Product in our data source are labelled from 010000-999999, with the first two-digits representing a general category to which the product belongs. Based on the 99 categories as extracted from the label, we further group the products into 18 most widely-accepted industries, as summarized in Table 1.

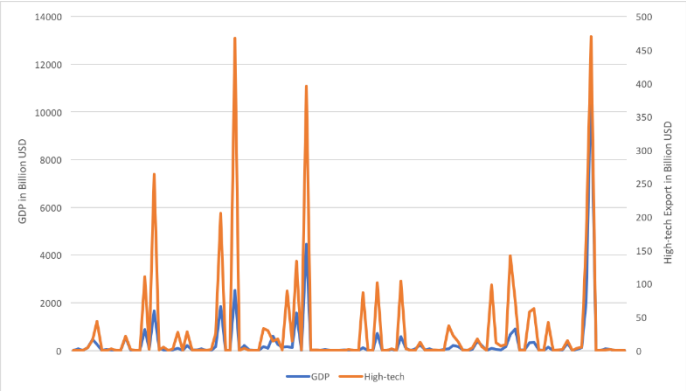

Note that the high-tech industry group is not a distinct industry but rather an aggregated industry that encompasses the most complicated products from the most technologically-advanced industries (as measured by PCI). This industry serves as an indicator for us to quantitatively evaluate how well a country has performed in developing cutting-edge technologies and closing its technical gap with advanced economies, which has become a topic of wide concern today. Indeed, when we rank the 18 categories based on PfCI (an

equivalent concept of PCI as calculated based on the 18 categorized product groups), high-tech industry has the highest PfCI among all industry groups.

Category	Description
Animal and By-product	All kinds of meat, livestock and related by-products
Vegetable, Fruit and Plant	All kinds of plants, edible vegetables and fruits
Food and Preparation	Edible preparations, raw cooking materials and appliances
Mineral and Stone	Mining industry for mineral and stone materials
Chemical	Raw chemical materials and by-products
Chemical Manufacturing	Advanced chemical products and pharmaceutical products
Raw Manufacturing	Basic products made from plastic, rubber, leather, etc.
Wood Product	Book, paper and other elementary products related to wood
Clothing and Accessory	All kinds of fabrics, filament, clothing and accessories
Textile	All kinds of textile articles and related products
Metal	Mining of all sorts of raw metal
Machinery	Machinery and mechanical appliances, including electrical equipment
Transportation	Vehicles and locomotives including aircraft, ship, railway, etc.
Weapon	Explosives, arms and ammunition
Daily Instrument	Basic daily instruments such as sport requisites, timing and measuring tools
Precious Stone	Refined or processed stone products such as pearl and ceramics
Service	Financial, business, legal, communication, travel services, etc.
High-tech	Agglomeration of advanced products with highest PCIs

Table 1: Categorization of Products

We further observe a strong positivecorrelation between the GDP and the export of high-tech products. As shown by Figure 4 below, a high adjusted R-square of 67.6% exists between GDP and high-tech exports, indicating that more successful economics, as measure by GDP, tend to be those that are capable of producing and exporting high-tech products as we define them.

Statistics	Value
Multiple R	0.824
R-Square	0.679
Adjusted R^2	0.676
Variable	**Value**
Coefficient	12.20
t-stat	15.61
P-value	0(***)

Figure 4: Regression of GDP and High-tech Exports

3.2 Actual Development

Based on the product categorization aforementioned, we aim to capture Malaysia's actual production strategy between 2009 and 2014 on a complexity level.In Hausmann and Hidalgo (2009), distance is defined to be a measure of how far a country is from a certain product not in its product space. We extend this concept to all product groups and quantify how technically equipped a country is to develop corresponding product groups. In other words, the shorter the distance between a country and a product group, the more capable a country is

in developing products within that group. Defining this net distance change as the Actual Developmental Index (ADI), our export data allows us to calculate and compare ADIofMalaysia and the 18 product groups in 2009 and 2014 through subtraction, where a positive ADI indicates a shortening of the distance (i.e., advancement of the industry), and a negative ADI indicates the reverse. As ranked in Table 2, during the period from 2009to 2014, Malaysia has focused on products with a low level of complexity and those requiring basicskills, including precious stone, vegetable, fruit and plant, as is expected for developing economies.

Category	ADI	Category	ADI
1. Precious Stone	0.015	2. Mineral and Stone	0.010
3. Vegetable, Fruit and Plant	-0.018	4. Chemicals	-0.023
5. Food and Preparation	-0.024	6. Weapon	-0.028
7. Animal and By-product	-0.031	8. Metal	-0.032
9. Daily Instrument	-0.033	10. Clothing and Accessory	-0.043
11. Wood Product	-0.044	12. Raw Manufacturing	-0.048
13. Transportation	-0.066	14. Textile	-0.077
15. Chemical Manufacturing	-0.088	16. Machinery	-0.099
17. Service	-0.107	18. High-tech	-0.114

Table 2: Actual Developmental Index (ADI) of Malaysia

3.3 Regional and Global Comparison

Table 3and 4 below summarizes how the production strategy adopted by Malaysia compares with its emerging counterparts and a selected group of leading economies in the world, as measured in ADI. It can be directly observed that Malaysia focused on products with a low complexity level, when compared against its emerging counterparts such as China and India, which give a considerable level of attention to intermediate-level product groups such as service and high-tech.

Ranking	Malaysia	China	Mexico	India
1	Precious Stone	Precious Stone	Vegetable, Fruit and Plant	Daily Instrument
2	Mineral and Stone	Service	Animal and By-product	High-tech
3	Vegetable, Fruit and Plant	High-tech	Chemicals	Wood Product
4	Chemicals	Machinery	Mineral and Stone	Machinery
5	Food and Preparation	Chemicals	Metal	Chemicals

Table 3: ADIComparison on a Regional Scale

Ranking	USA	Germany	Singapore	France
1	Service	Chemicals	Machinery	Raw Manufacturing
2	Chemical Manufacturing	Service	Transportation	Mineral and Stone
3	Food and Preparation	High-tech	Daily Instrument	Precious Stone
4	Textile	Transportation	Chemicals	Chemical Manufacturing
5	Clothing and Accessory	Food and Prep	High-tech	Chemicals

Table 4: ADI Comparison on a Global Scale

Table 4 further examines Malaysia's development strategy against those of more developed economies on a global scale. Reasonably, developed economics such as USA, Germany,

Singapore and Japan have devoted the majority of their efforts into highly complicated industry groups while emerging economies such as Malaysia still partially relies on basic industry groups like mineral and stone. This trend holds true in general, regardless of the continent or the time period, and serves as an indicator for which phase of development a country is currently in as evaluated from their production strategy. Based on this standard, Malaysia is indeed adopting an unambitious strategy that seeks development in industry groups with a low level of complexity.

4. Product Space Design

4.1 Suggested Development Vector

As aforementioned, distance gives us an idea of how far each new product is from a country's current mix of exports. As defined in Hausmann and Hidalgo (2009), distance is "the weighted proportion of products connected to goods p that country c is not exporting, i.e., MCP=0." Based on this definition, the distance between a country and any product that the country is currently exporting (i.e., the country is a significant exporter in the product as compared to global average) is zero. Similarly, opportunity gain quantifies the contribution of a new product in term of opening up the doors to more and more complex products. Intuitively, a product that a country is currently exporting (i.e., MCP=1) has an opportunity gain of zero. And unreasonable investment on certain product p would lead to a relative decrement in export of more profitable products, and therefore lead to a negative opportunity gain of product p. The opportunity gain is not the only estimator of a country's level of economic development. However, among countries with comparable economics strength, those having higher ECI, or in other words, more reasonable economics structure is often in better shape.

Ranking	Mexico	Japan	South Korea	Germany	China	Malaysia	France
1	Vegetable, Fruit and Plant	Daily Instrument	Chemicals	Mineral and Stone	Mineral and Stone	Raw Manufacturing	Service
2	Daily Instrument	Transportation	Daily Instrument	Chemicals	Clothing and Accessory	Daily Instrument	High-tech

Table 5: SDV of High E_fCI Countries 2014

We define the ranking of opportunity gain for a country c, as the Suggested Development Vector (SDV) of c. Table 5 shows the SDV of a selected group of leading economies with outstanding economic complexity, with the industry groups ranked in decreasing order of significance. Dark grey indicates positive opportunity gain, gray indicates zero opportunity gains, and light grey indicates negative opportunity gains. The result shows that leading countries barely have any industries with positive opportunity gain. In other words, those countries are already in the most stable and efficient economic structure. Without the necessity of economic transition, those countries merely need to maintain a steady and balanced economic development. In contrast, countries listed in Table 6 have nearly half of

industries with positive opportunity gain. While the economies with absolute negative E_fCI, such as Nigeria and Algeria, all need to develop High-tech, machinery and daily instruments, those with median E_fCI are facing a more complicated and diverse situation, such as Italy, Spain and USA.

It can be concluded that Malaysia is categorized to be a highly complexed country as compared with the world's leading economies and other major economies in Europe.

Ranking	Italy	Spain	USA	Nigeria	Algeria
1	Mineral and Stone	Mineral and Stone	Machinery	High-tech	High-tech
2	Chemicals	Precious Stone	High-tech	Machinery	Machinery

Table 6: SDV of Other Typical Countries 2014

4.2 Sensitivity Analysis and Contingency Strategy

Malaysia has a characteristic SDV of high-complexity economy and is embedded with massive production knowledge. Malaysia should take precautions against unexpected strikes industry by industry and forecast the adverse effects. The regression of an industry with low PCI and low Opportunity Gain is less dangerous than that of cornerstone industries. High-tech is such a representative of the cornerstone industries, because High-tech connects to most of the profitable products that developed countries are currently specializing in. For the same token, Food and Preparation is one of the less fundamental industries for developed countries. Such intuition can be rigorously proved by the sensitivity analysis we are about to implement.

The sensitivity analysis aims to approximate the volatility of SDV subject to an instant increment or decrement of export and is mainly implemented on developed countries that have few industries with positive opportunity gains. To be more specific, sensitivity score is the least-squared slope for the linear regression between percentage change of production for Country C and Product P and the E_f CI of C.

When the opportunity gain of the industry is negative, the sensitivity analysis approximates how an over-development of the industry jeopardizes the economic structure of a country. When the opportunity gain of the industry is zero, the sensitivity analysis determines whether the further development of the industry shapes the country a better economic structure, and predicts how the SDV would change accordingly. Specifically, as we reduce the export of

such an industry to 25%-50% of its original value, a few other industries originally with negative opportunity gain would probably become profitable. We separate the increment and decrement of production in the sensitivity analysis, because they tend to show vast difference. The considerable profitability of a production spike doesn't imply a shrink is always followed by a painful crisis.

We perform the sensitivity analysis of the aggregate of top ECI countries, including US, UK, Korea, Japan, South Korea, Singapore, Germany, and France, and use the result as the benchmark. The sensitivity score in 2014 and 2009 are shown in Table 7 and Table 8 respectively:

	High-tech	Food and Preparation
Decremental	1.676	0.007
Incremental	1.195	-0.006

Table 7: Sensitivity Score of the Aggregate of Developed Countries 2014

	High-tech	Food and Preparation
Decremental	1.514	-0.001
Incremental	1.294	0.007

Table 8: Sensitivity Score of the Aggregate of Developed Countries 2009

In summary, High-tech exerts great impacts on economics structure of top countries. Such countries are extremely vulnerable to High-tech industry declines, and benefit from High-tech prosperity. In contrast, ECI is not highly sensitive to shift of Food and Preparation industry.
We observe a similar pattern that the Sensitivity Score of Food and Preparation is approximately zero, while the Decremental Sensitivity Score is larger than the Increment. We can therefore make three conclusions here.

1. The disturbance in Food and Preparation industry exert a trivial impact on the E_fCI of a country, which echoes with our intuition that Food and Preparation is of minimal significance to the structure of product space of developed countries or fast developing countries.
2. The High-tech industry is the cornerstone industry of most developed or fast developing countries.
3. The reward of an increase of High-tech production is less than the jeopardy of a decrease in the same extent.

Besides the sensitivity score, we are interested in the shift of SDV caused by upheavals in different industries. The shift of SDV gives us a good vision of how the production pattern will be affected. The results of Benchmark in 2014 are shown below in Table 9-Table 16

Table 16: Aggregated Food and Preparation 2009 (Incremental Sensitivity)

The Contingency Plan aims to present a set of solutions with respect to upheavals in different industries. Instead of compensating for the declining production directly, the best strategy is to develop those incipiently profitable industries. In this manner, we can derive the contingency strategy for countries to deal with possible abrupt declines of crucial industries. In some cases, the SDV remains unchanged even when a zero-opportunity-gain industry declines to its 20% in terms of export. We can then conclude the industry is not indispensable to the country. As a clarification, the three consecutive N/As means that the country doesn't even need to respond to a collapse in the industry. Countries tend to have distinct solutions to the up and down of the same industry.

4.3Result and interpretation

The sensitivity analysis of Malaysia ends up with the results below.

	High-tech	Food and Preparation
Decremental	2.029	0.000
Incremental	0.306	-0.055

Table 17: Sensitivity Score of Malaysia 2014

	High-tech	Food and Preparation
Decremental	1.420	0.000
Incremental	0.351	-0.133

Table 18: Sensitivity Score of Malaysia 2009

Malaysia has sensitivity scores typical to developed countries. Malaysia is barely influenced by the flucuation in Food and Preparation industry, while is subject to the up and down in High-tech. However, Malaysia is obviously more sensitive to High Tech downturns in 2014. One possible explanation is that the economic struture of Mexico deteriorates from 2009 to 2014, because of its neglection of Daily Instrument, and Machinery. Therefore, a sudden decline of High Tech industry would further deteriorates Malaysia's economic balance.

Table 22: Malaysia High Tech 2009 (Incremental Sensitivity)

As shown in Table 19---Table 22 above, the economy of Malaysia is in a much more sensitive and fragile state in 2014, compared to 2009. Even if the High Tech industry has some surprising breakthroughs, the Malaysia still cannot receive enough stimulations in other relevant industries.

Decreasing export of each industry in Malaysia's current production space by 60% respectively, we derive the contingency strategy shown below in Table 14.

Table 24: Contingency Table of Malaysia during Industry Strikes 2009

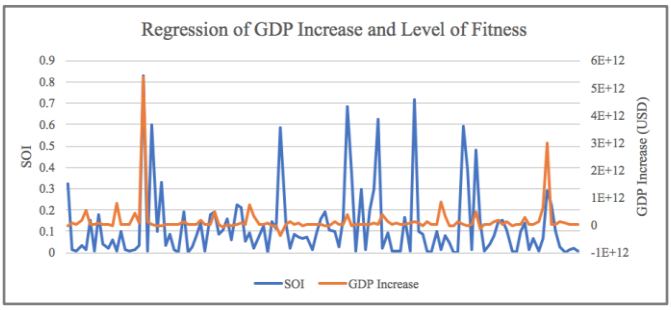

Developing Precious Stone, Weapon and Animal and by-Product is the solution to declines in High tech and Machinery in 2014. In 2009, however, Malaysia a extremely stable SDV.

5. Macro-level Predictions

5.1 Structural Optimality Index

Indeed, such choice of prioritization has proven to be a significant factor in deciding the economic outcomes of countries. In order to quantitatively evaluate how effective our developmental strategies are and how deviations from the suggested developmental path will lead to non-optimal growth results, we define the measure – Structural Optimality Index (SOI) – on a country level as the R-Square obtained from regressing the country's actual development over the suggested development strategy. Both strategies are quantified in nature, with the actual development represented by export increase in major industry groups and the suggested development strategy represented by the opportunity gains of developing the corresponding industry groups as calculated in previous sections. The R-square from the regression thus provides us with a concrete measure of how the development path adopted by the country has fitted with/differed from our suggestion.

After obtaining this measure for all countries in our database, we further regress countries' five-year economic growth, which as defined as the net increase in GDP (USD), over their SOI. Figure 6 illustrates the regression output, which shows a strong positive correlation between countries' level of fitness and their five-year GDP growth, significant at the 1% level and achieving an adjusted R^2 of 11.9%. In other words, the more a country develops as suggested by calculations on a complexity level, the better economic outcomes it achieves.

Statistics	Value
Multiple R	0.355
R-Square	0.126
Adjusted R^2	0.119
Variable	**Value**
Coefficient	$1.249*10^{12}$
t-stat	4.061
P-value	0.000(***)

Figure 6: Regression of Five-year GDP Growth over SOI

5.2 SOI of Malaysia and Its Implications

Malaysia, for instance, has a moderate level of structural optimality. As the regression in Figure 7 suggests (the orange curve represents export increase and the blue curve stands for opportunity gain of the corresponding industry), Malaysiademonstrates a promising level of correlation with the suggested developmental path, having an adjusted R-square of around 10.2%. Malaysiaranks the 42^{ed} place among all countries in terms of SOI and has an annual growth rate of 10.8% from 2009 to 2014, which is consistent with the regression result in Figure 6. This is in direct contrast to developed economies such as UK, where there is low SOI of around 6.5% and a corresponding annual growth rate around 2%, ranking it a slow-developing economy during the period. In sum, Malaysia's amazing economic progress from 2009 to 2014 can be at least partially explained by a nearly optimal development strategy that demonstrates a considerable level of matches with our suggested developmental path.

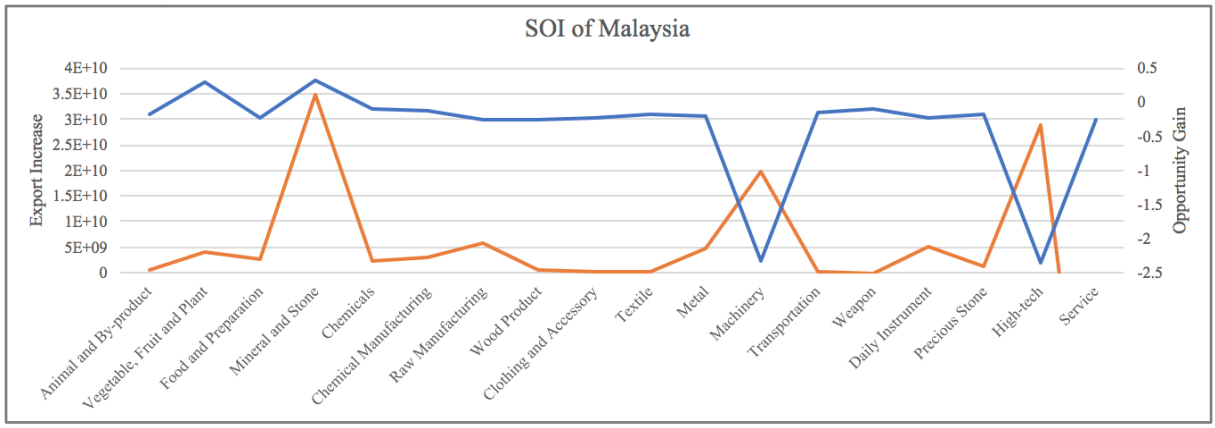

Figure 7: SOI ofMalaysia (2009-2014)

6. Concluding Remarks

In conclusion, Malaysia has demonstrated a surprising level of economic growth in terms of GDP during the period from 2009 to 2014, concurrent with anincrease in economic complexity as compared with other major Asianor emerging economies in the world.

The amazing progress made during the period, we believe, can be largely explained through analysis of the economic and product complexity structure of Malaysia on the industry group level. The product classification system we adopt allow us to measure the actual development for various industry groups and to observe that Malaysia strategically invested in developing basic industry groups such as stone, food and chemicals during the period, while its Asian counterparts and emerging economies around the globe have adopted much more aggressive growth paths.

Based on our analysis of the opportunity gain and a sensitivity analysis of major industry groups, Malaysia could further its gains by staying optimal with its current industry structure and there is no immediate need of reform because no industry has a positive opportunity gain at its current stage. We further note that Malaysia has a slightly mismatched development strategy that indicates a moderate level of fitness with the strategy calculated on a complexity level, having an adjusted R-square of around 10.8%. Since a significant positive correlation exists between five-year GDP growth and the structural optimality index of an economy as we define and calculate, Malaysia indeed adopted a promising but not perfect development plan as compared with other emerging economies both on a regional scale and on a global scale, and has the potential to further its economic gains through industrial structure balancing as suggested in the paper.
